## Part 1 Dataset Loading

In order to learn how to use RStudio for graph analysis, I used the dataset of Arxiv GR-QC (General Relativity and Quantum Cosmology) collaboration network. This dataset contains 5242 nodes and 14496 edges in total and covers papers in the period from January 1993 to April 2003 (124 months).

### a. Loading Approach 1: Import

File → Import Dataset → From Text (base)

### b. Loading Approach 2: read.table() function

```
CA.GrQc = read.table(file="CA-GrQc.txt", header = TRUE, comment.char="#")
```

Then I got a dataframe variable named 'CA.GrQc'.

## Part 2 Initial Graph Plotting

I installed the igraph package from CRAN mirrors using the `install.package()` function and loaded the package by `library()` function. Before continuing, I was required to convert the dataframe into an igraph format using `graph_from_data_frame()`. I named this object 'graph' and then used `plot.igraph()` to create the plot for the entire dataset as shown in Figure 1.

Figure 1. Raw Dataset

Due to the large amount of data, I can hardly observe the data structure, even though I set parameters like 'vertex.label.cex' and 'vertex.size', to view the graph more clearly (Figure 2).

Figure 2. Raw Dataset (Clearer Version)

## Part 3 Dataset Simplifying and Plotting

To solve the problem described above, I took the following steps towards graph simplification:

- Step 1. Choose the nodes with degree greater than or equal to 20 and plot the graph.

Code Implementation:

```
vertices_lt20 = V(graph)[igraph::degree(graph)<20]  
graph1 = igraph::delete.vertices(graph,vertices_lt20) #remove nodes (degree <=20)  
plot.igraph(graph1, edge.arrow.size=0.3, vertex.size=10, vertex.label.cex=0.5)
```

Plot Result as Figure 3:

Figure 3. Simplify-Step 1

It is still hard to see the internal structure, so I continue to step 2.

- Step 2. Choose the first 200 edges and plot the graph.

Code Implementation:

```
graph1_df = as_data_frame(graph1, what="edges") #convert igraph object to dataframe  
graph2_df = graph1_df[1:200,] #choose the first 200 edges  
graph2 = graph_from_data_frame(graph2_df)  
plot.igraph(graph2, edge.arrow.size=0.3, vertex.size=10, vertex.label.cex=0.5)
```

Plot Result as Figure 4:

Figure 4. Simplify-Step 2

Now the structure is become clearer, but I can still simplify some more.

- Step 3. Choose the nodes with degree larger than 2 and plot the graph.

Code Implementation:

```
vertices_lt2 <- V(graph2)[igraph::degree(graph2)<2]
graph.sim = igraph::delete.vertices(graph2, vertices_lt2)
plot.igraph(graph.sim, edge.arrow.size=0.3, vertex.size=10, vertex.label.cex=0.5)
```

Plot Result as Figure 5:

Figure 5. Simplify-Step 3

Finally, I arrive at a three-cluster igraph object for deeper analysis and plotting.

- Vertices of the Graph

- Edges of the Graph

- Adjacency Matrix: Indicates which vertices are connected by edges

[ reached getOption("max.print") -- omitted 25 rows ]

- Density: Gives us the ratio of edges in the graph vs the maximum number of possible edges in a graph. When loops = T this means that the maximum counts self-loops.  
Note: I use as.matrix() for compatibility with the sna functions.

```
> graph.sim.adj = as.matrix(get.adjacency(graph.sim))
> graph.sim.density = gden(graph.sim.adj)
> graph.sim.density
[1] 0.05072464
> edge_density(graph.sim)
[1] 0.05072464
> edge_density(graph.sim, loops=T)
[1] 0.04962193
```

- Egocentric Network and Degrees: Creates a subgraph of a given node and its immediate neighbors. At the bottom there is the number of degrees per node, which is a measurement of the number of edges connected to it

```
> graph.sim.ego = ego.extract(graph.sim.adj)
> graph.sim.ego["8612"]

```

- Betweenness Centrality: The betweenness centrality is measured through the number of times a node is present in the shortest path. The centralization is the graph level centrality, and the theoretical max is the maximum possible centrality for a graph with these parameters

```

## Part 4 Explore Functions

Igraph is a powerful package which contains over 700 functions for graph plotting. I chose to explore and exercise by 11 of them.

- Look at more available layouts in igraph

```
> layouts = grep("^layout_", ls("package:igraph"), value=TRUE)[-1]
> # Remove layouts that do not apply to our graph
> layouts = layouts[!grepl("bipartite|merge|norm|sugiyama|tree", layouts)]
> par(mfrow=c(3,3), mar=c(1,1,1))
> for (layout in layouts) {
+   print(layout)
+   l = do.call(layout, list(graph.sim))
+   plot(graph.sim, edge.arrow.mode=0, layout=l, main=layout, vertex.label = NA) }
[1] "layout_as_star"
[1] "layout_components"
[1] "layout_in_circle"
[1] "layout_nicely"
[1] "layout_on_grid"
[1] "layout_on_sphere"
[1] "layout_randomly"
[1] "layout_with_dh"
[1] "layout_with_drl"
[1] "layout_with_fr"
[1] "layout_with_gem"
[1] "layout_with_graphopt"
[1] "layout_with_kk"
[1] "layout_with_lgl"
[1] "layout_with_mds"
```

- Reset the graphical parameters

```
> dev.off()
null device
  1
> par(mfrow=c(1,1))
```

- Interact with the plotting of networks

```
#tkid is the id of the tkplot that will open
tkid = tkplot(graph.sim)
```

```
> # grab the coordinates from tkplot
> tkplot.getcoords(tkid)

```

- Create a heatmap of the network matrix

```
> pal = colorRampPalette(c("gold", "dark orange"))
> heatmap(graph.sim.adj, Rowv = NA, Colv = NA, col = pal(5), scale="none", margins=c(10,10))
```

- Reciprocity: the proportion of reciprocated ties

```
> reciprocity(graph.sim)
[1] 0.247619
```

- Transitivity: which is calculated according to two different ways: global and local

```
> #global - ratio of triangles (direction disregarded) to connected triples.
> transitivity(graph.sim, type="global")
[1] 0.2982456
>
> #local - ratio of triangles to connected triples each vertex is part of.
> transitivity(graph.sim, type="local")
Transitivity works on undirected graphs only. The result might be incorrect if the graph includes mutual edge pairs or multiple edges between the same pair of vertices. igraph 1.3.0 and later will treat this as an error.

> plot(graph.sim, vertex.size=as*15, main="Authorities", edge.arrow.size=0.3, vertex.label.cex=0.5)
```

## Hubs

## Authorities

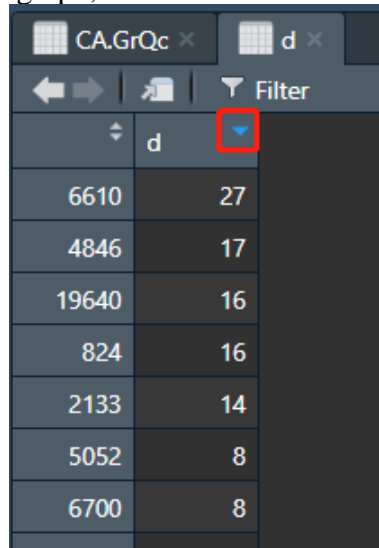

## Part 5 Determine Several Technical Values

(a) central node(s)

Code Implementation:

```
d = igraph::degree(graph.sim)
d = as.data.frame(d)
```

The central node is the nodes with the high number of degrees in the graph. For this question, I took the degrees of each node and used the sorting tool within R to find the largest value. For our graph, the central node is 6610.

	d
6610	27
4846	17
19640	16
824	16
2133	14
5052	8
6700	8

Figure 6. Dataframe of Degree

(b) longest path(s)

Code Implementation:

```
igraph::diameter(graph.sim)
diam = get_diameter(graph.sim, directed=T)
diam
```

I can get the length of the longest path simply by using the diameter function in igraph. I can also use get\_diameter to get the nodes that follow this longest path. For this graph, I have a longest path of length 4 using the following sequence of nodes shown in Figure 7.

```
> igraph::diameter(graph.sim)
[1] 4
> diam = get_diameter(graph.sim, directed=T)
> diam
+ 5/46 vertices, named, from ca05217:
[1] 10310 19640 6610 4846 7350
```

Figure 7: Longest Path Calculation

(c) largest clique(s)

Code Implementation:

```
vcol = rep("grey80", vcount(graph.sim))
vcol[unlist(largest_cliques(graph.sim))] = "gold"
plot(as.undirected(graph.sim), vertex.color=vcol, vertex.label.cex=0.5, vertex.size=15)
```

Plotting Result:

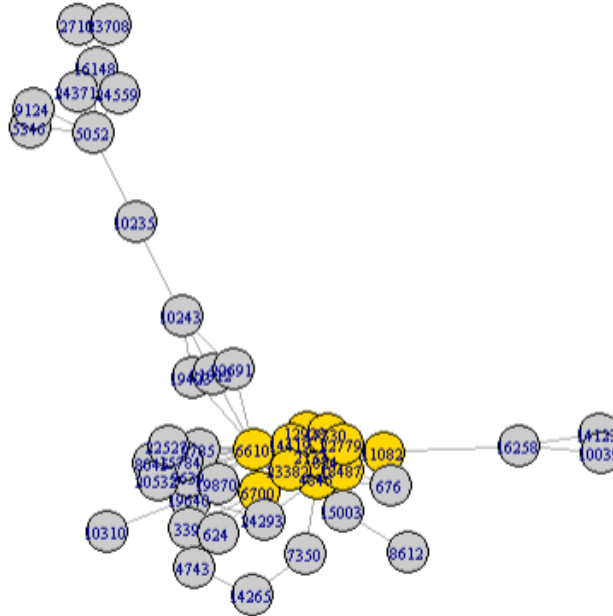

Figure 8: Largest Clique (Gold)

(d) ego(s)

I can find the biggest immediate neighborhood for all nodes by ego() function, here I only show the result for our central node: 6610.

```
> ego(graph.sim, nodes=V(graph.sim)["6610"])
[[1]]
+ 24/46 vertices, named, from 4df0ba4:
 [1] 6610 19640 4846 824 2133 6700 8045 9639 9785 15784 19870 20532 22527 19423 21012 22691
[17] 15003 11082 12928 14419 17330 18487 22779 23382
```

Figure 9: Ego for node 6610

(e) power centrality

power centrality takes a graph (data) and returns the Boncich power centralities of positions (selected by nodes).

Code Implementation:

```
pc = power_centrality(graph.sim, exponent = 0.9)
pc_df = as.data.frame(pc)
pc_df <- cbind(node = rownames(pc_df), pc_df)
rownames(pc_df) <- 1:nrow(pc_df)
pc_df[which.max(pc_df$pc),]
```

Using `power_centrality()` from the `igraph` package, I am able to calculate the power centrality for each node in the graph, as well as the central node. Note: I must set `exponent = 0.9` to avoid an error

```
> power_centrality(graph.sim, exponent = 0.9)

Figure 10b: Central Node using Power Centrality

## **Part 6 Discussion and Conclusion**

For this project, I loaded a large data set of authors and co-authors into a graph using the igraph package in R. Since this dataset contained over 5000 nodes and 14000 edges, it was clear I would need to implement some graph simplification strategies.

I applied multiple strategies before successfully completing our simplification. Firstly, I ordered our nodes based on frequency and selected the top 300 authors. This strategy helped simplify our graph, but I was concerned this would not have enough randomness within the sample. Instead, I selected 400 nodes randomly, and then reduced this number by mandating the nodes have at least one degree. This strategy performed better, but resulted in a graph containing two subgraphs, and I preferred to work with just one. The final strategy had us performing degree removal first, dropping all nodes with less than 20 degrees, then I took the first 200 nodes of the resulting graph and dropped the remaining nodes with less than 2 degrees. The result was the graph shown in Figure 5, which contains 46 vertices, 105 edges, and no subgraphs, this is the graph I used for the remainder of our analysis

The rest of our analysis includes practicing with the igraph functions mentioned in the rubric, as well as some others. This exploration helped us become much more comfortable working with, visualizing, and understanding graph. The functions made it easier for us to identify and label cliques that occurred within the dataset. I also learned how to use different measurements for centrality, including closeness, betweenness, alpha, and power centrality. Finally, I learned the difference between directional measurements, such as hubs and authorities, and how to represent them in our graph.
